Hello,

I would like to suggest a great improvement that could be added to WE in order to manage the traceability.

Developers shall be able to answer to that simple question: which documentation set applies for that software release?

Redmine already manages a kind of traceability for wikis, but only at the page scope, not at the wiki scope.

One simple solution would be to add a git-style tag feature, in order to "take a snapshot" of the full project at software delivery time.

I'm currently thinking about adding tags with a simple MySQL query inside the "comment" field of wiki pages.

That way it will be easy to have a full traceability of the doc set, just looking at the history of the wiki page.

Next step would be to be able to roll back and forward into wikis snapshots, as easy as switching between branches with GIT, but maybe it's an other story...
